_____________________________________________________________________________________________________

(ii) Cell Y is a guard cell.

State, using only the information in Fig. 4.1, one adaptation of this cell and explain how the adaptation allows the cell to carry out its function.
(b) Fig. 4.2 shows drawings of the six chromosomes inside an animal cell viewed during late prophase of mitosis.

Fig. 4.2

(i) Identify one pair of homologous chromosomes in Fig. 4.2 by drawing around each chromosome in the pair on the diagram.

(ii) The nucleus of a sperm cell is produced by meiosis.

Draw a diagram in the space below to represent the chromosomes that are present in the nucleus of a sperm cell from the same animal.
Question: 2

(a) (i) Name the process by which water leaves a cell.
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

(ii) Describe the routes that water molecules take through the cell surface membrane.

[1]

A student carried out an investigation to determine the effects of different sucrose concentrations on cells from pieces of onion epidermis.

• Strips of epidermis were taken from an onion.
• Separate pieces of epidermis were placed into water and a range of sucrose solutions.
• The pieces of epidermis were left for 30 minutes before being removed.
• The pieces of epidermis were then viewed at high power under the microscope.

The student counted 100 cells from each piece of epidermis. The student noted how many cells had become plasmolysed.

The results are shown in Table 6.1.

<table>
<thead>
<tr>
<th>concentration of sucrose solution (mol dm⁻³)</th>
<th>water potential of sucrose solution (kPa)</th>
<th>percentage of cells plasmolysed (%)</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

Table 6.1
None of the onion epidermis cells this student observed had burst when left in pure water. Explain why plant cells do not burst when they are left in pure water.

The water potential of the onion epidermis cells can be assumed to be the same as the water potential of a solution that causes 50% plasmolysis. Use the information in Table 6.1 to estimate the water potential inside these onion epidermis cells.

Suggest how the student could construct and use a graph to obtain a better estimate of the water potential.

Suggest how the student could modify the procedure to make the results more reliable and accurate.
(a) Name the type of nuclear division that produces two genetically identical nuclei.

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

(b) There are a number of stages during cell division.

The list, J to N, describes some processes that occur during the division of an animal cell.

<table>
<thead>
<tr>
<th>J</th>
<th>the cell surface membrane is constricted</th>
</tr>
</thead>
<tbody>
<tr>
<td>K</td>

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

(c) As part of an allergic response, certain cells in the lungs release histamine.

Histamine is a cell signalling molecule that stimulates smooth muscle in the wall of structure A to contract.

Suggest how histamine stimulates smooth muscle contraction.

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

[2]
(d) Another action of histamine is to make capillary walls more permeable.

Suggest **two** effects this increased permeability may have on the surrounding tissues.

[2]

[Total: 8]
Large, active organisms need a circulatory system because they have a small ___.

Haemoglobin is a pigment found in red blood cells. These cells are also known as ___ Haemoglobin has a high ___ for oxygen. In the lungs, the haemoglobin associates with oxygen to form ___.

In respiring tissues, the oxygen is released by dissociation. In very active tissues, the amount of oxygen released can be increased by the presence of more ___.

This is called the ___ effect. [6] [Total: 6]
The use of microscopy has greatly enhanced our knowledge of cell structure.

(a) Explain the difference between magnification and resolution.

(b) State the resolution that can be achieved by each of the following types of microscope.

light microscope

transmission electron microscope

(c) Fig. 4.1 is an electron micrograph showing part of a nucleus.
(i) A student stated that Fig. 4.1 was taken using a scanning electron microscope.

What evidence supports the student’s statement?

(ii) On Fig. 4.1, the nuclear pore complex, labelled A, is 3 mm wide.

Calculate the actual diameter of the pore, in nanometres.

Answer

(iii) State the function of the nuclear pores.
(d) State two features of a eukaryotic cell, other than nuclear pores, that would not be visible using medium power of a light microscope.
A student used a potometer to investigate the effect of light intensity on the rate of transpiration in a healthy leafy shoot. The results obtained are shown in Table 5.1.

**Table 5.1**

[Total: 11]
Question: 8

Fig. 1.1 shows an air sac and a capillary in the mammalian lung.

(a) The mammalian lungs contain many air sacs.

(i) Name the air sacs and state why there are many air sacs in the lungs.

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

(ii) Name the type of epithelium in the walls of the air sacs.

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

(iii) The air sacs contain many elastic fibres.

Explain the role of these elastic fibres during ventilation.

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
(b) For efficient gaseous exchange to occur, a steep diffusion gradient must be maintained between the air in the air sacs and the blood.

A steep diffusion gradient can be maintained by ventilating the lungs. This refreshes the air in the air sacs.

(i) Explain how refreshing the air in the air sacs helps to maintain a steep diffusion gradient.

(ii) Describe and explain one other way in which a steep diffusion gradient is maintained in the lungs.

[Total: 9]
(a) Complete the following paragraph about cells by using the most appropriate term(s).

Cells that are not specialised but still have the ability to divide are called _______ cells. Such cells can be found in the _______ of the long bones of mammals. These cells can _______ into other types of cell, such as erythrocytes that carry oxygen in the blood. In plants, _______ tissue also contains cells that are not specialised.

(b) Sponges are simple eukaryotic multicellular organisms that live underwater on the surface of rocks. Sponges have a cellular level of organisation. This means that they have no tissues. Each cell type is specialised to perform a particular function.

One type of cell found in a sponge is a collar cell. Collar cells are held in position on the inner surface of the body of the sponge. Fig. 2.1 is a diagram showing a vertical section through the body of a sponge and an enlarged drawing of a collar cell.

Fig. 2.1

(i) Suggest one function of the flagellum in the collar cell.

_____________________________________________________________________________________________________

_____________________________________________________________________________________________________
(ii) Suggest one possible role for the collar of mucus in the cell.

(c) In more advanced organisms, cells are organised into tissues consisting of one or more types of specialised cells. Describe how cells are organised into tissues, using xylem and phloem as examples.
Question: 10
Three examples of fluids in the mammalian body are blood, tissue fluid and lymph.

(a) Complete Table 3.1 below comparing different features of arterial blood, tissue fluid and lymph.

<table>
<thead>
<tr>
<th>feature</th>

_____________________________________________________________________________________________________

_____________________________________________________________________________________________________

_____________________________________________________________________________________________________

Membranes are a fundamental part of the cell. They are found both at the surface of a cell and inside a cell.

(a) State three roles of membranes inside cells.

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

(b) Cells contain a large number of membrane-bound vesicles. Many of these vesicles transport substances between organelles.

(i) Outline how the vesicles are moved from one organelle to another.

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

(ii) The proteins embedded in the membranes of vesicles have different functions.

- COPI and COPII proteins are known as ‘address proteins’

- Vesicles that transport materials from the Golgi to the rough endoplasmic reticulum (RER) are coated in COPI proteins.

- Vesicles that transport materials to the Golgi from the RER are coated in COPII proteins.

Suggest how these proteins ensure that a vesicle is transported to the correct target organelle.

</tbody>
</table>

(i) Calculate the mean value for the rate of transpiration at 16.00 hours.

Give your answer to **one decimal place**.

Answer =

(ii) Explain why, for each time of the day, the student carried out three replicates to calculate a mean.

(iii) Suggest **two** possible reasons, other than light and temperature, why the rate of transpiration was **lower** in the afternoon than in the morning.

1

2
(iv) Explain why the potometer only gives an estimate of the rate of transpiration.
(a) Fig. 4.1 is a diagram showing the position of the vascular bundles in a transverse section of the stem of a young dicotyledonous plant.

![Diagram of a transverse section of a stem]

Select the correct letter from Fig. 4.1 to identify each of the following tissues in the stem.

- **xylem**
- **phloem**
- **cambium**

(b) Fig. 4.2, on the insert, shows the cut end of a stem from a woody plant. The other end of the stem is being heated in a fire. Steam can be seen coming from the vascular tissue at the cut end of the stem.

Describe the features of the xylem that enable the steam to pass from the heated end of the stem to the cut end.

(c) (i) Define the term transpiration.
(ii) Describe and explain how transpiration contributes to the mechanism of water transport up the stem.

In your answer, you should use appropriate technical terms, spelt correctly.

(iii) Suggest why a bunch of flowers may survive longer if the ends of the stems are removed immediately before the flowers are placed in water.

[4]

[Total: 8]
(a) Fig. 1.1, on the insert, shows an electron micrograph of cells from the liver.

(i) Some cells, such as liver cells, contain a lot of Golgi apparatus.

State **one** function of the Golgi apparatus.

(ii) Suggest why the nuclear envelope contains pores.

(iii) State the function of the lysosomes.

(b) The liver is an organ.

Explain what is meant by the term **organ**.
(c) Using the mammalian gaseous exchange system as an example, explain how the different cells and tissues enable the effective exchange of gases.

In your answer, you should use appropriate technical terms, spelled correctly.
The cell surface membrane allows different substances to enter and leave the cell.

(a) List three components of a cell surface membrane.

(b) (i) Explain what is meant by the term active transport.

(b) (ii) State two examples of active transport in cells.

For each example, you should name the substance that is transported and the cell involved.

(c) In addition to active transport, substances can pass through cell surface membranes by:

- diffusion
- facilitated diffusion
- osmosis
- bulk transport (endocytosis / exocytosis)

For each example described in Table 2.1 below, state how the substance crosses the cell surface membrane. The first one has been done for you.

<table>

(b) The pressure fluctuates as the blood flows along the aorta, as shown in Fig. 3.1.

(i) Explain what causes this fluctuation.

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

[1]

[2]
(ii) State the term used to describe the number of fluctuations per minute.

[1]

(c) Using the information in Fig. 3.1, describe the pressure changes in the blood as it flows through the circulatory system from the aorta to the veins.

[3]

(d) (i) Using the information in Fig. 3.1, explain what causes the overall change in pressure as blood flows from the aorta to the arteries and from the arteries to the capillaries.

[2]

(ii) Explain why it is important that the pressure changes as blood flows from the aorta to the capillaries.

[2]

[Total: 11]
(a) Complete the passage below.

Membranes have a variety of functions in cells. All membranes are permeable. This means that they allow the passage of certain substances by processes such as active transport or through the membrane. The cell surface membrane, also known as the membrane, surrounds the cytoplasm.

The cell surface membrane consists of a bilayer of . To stabilise the structure of the membrane and keep it fluid, molecules of are also found in this bilayer.

(b) Membranes contain a variety of proteins. Some of these proteins are combined with carbohydrates to form glycoproteins.

Describe the functions of glycoproteins in the cell surface membrane.

In your answer you should use appropriate technical terms, spelt correctly.
Fig. 6.1 is a diagram of a spirometer, a piece of apparatus used to measure some aspects of breathing, such as breathing rate and vital capacity.

(a) (i) Outline the mechanism of inspiration.

In your answer you should use appropriate technical terms, spelt correctly.

(ii) A person breathes through the mouthpiece of a spirometer. State what happens to the air chamber in Fig. 6.1 during inspiration.

(iii) Chamber T contains a chemical that absorbs carbon dioxide. Suggest a chemical that could be used in chamber T to absorb carbon dioxide.

(b) Explain why a person using the spirometer to measure their vital capacity should wear a nose clip.
(c) State two other precautions that should be taken when using a spirometer to measure vital capacity.

(c) Fig. 1.1 is an electron micrograph of xylem tissue in the stem of a plant.

Fig. 1.1

(i) State one function of xylem tissue.

---
---
---
---
---
---
---
---

(ii) The spiral band in the xylem vessel shown in Fig. 1.1 contains a substance called lignin. State the function of this spiral band of lignin and explain why it is important that the xylem vessel becomes lignified in this way.

(iii) Explain the function of the pits seen in Fig. 1.1.
Fig. 2.1 shows the structure of a plasma (cell surface) membrane.

(a) (i) Name the components of the plasma (cell surface) membrane labelled D, E and F.

D

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

E

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

F

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

(ii) State one function for each of the components D, E and F.
(b) Glycoprotein molecules are positioned in the plasma (cell surface) membrane with the carbohydrate chain outside the cell. This is to allow the glycoproteins to act as receptors in the process of cell signalling.

(i) Explain what is meant by the term cell signalling.

(ii) Explain how a glycoprotein can act as a receptor.

(c) A student investigated the effect of temperature on the release of pigment from pieces of beetroot. She cut a fresh beetroot into four pieces and placed each piece into water at a different temperature. After 10 minutes she removed the beetroot and used a colorimeter to test how much pigment had entered the water.
She placed the coloured water into the colorimeter and measured the percentage transmission of light through the water. Her results are shown in Table 2.1.

Table 2.1

<table>
<thead>
<tr>
<th>temperature of water (°C)</th>

<td>0</td>
</tr>
</tbody>
</table>

(i) The results show that below 50 °C little pigment had entered the water. Explain why there was no transmission of light after the beetroot had been placed in water at 100 °C.

(ii) Suggest three ways in which the student could have improved her investigation.

1

2

3
(a) Complete the following paragraph about the loss of water from plants.

The loss of water from the aerial parts of a plant is known as [leaf transpiration]. The majority of water is lost from the leaves. Water is transported up the stem in the [vascular bundles] and passes into the mesophyll cells of the leaf by [through the xylem]. Water evaporates from the surface of these cells. From the air spaces in the leaf, the water vapour diffuses out of the leaf through the [stomata].

(b) (i) Explain why water loss from the leaves of a plant is unavoidable.

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

(ii) Name the [type of plant adapted to reduce water loss from its leaves].

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

(iii) State and explain two adaptations of leaves that reduce evaporation.

In your answer, you should use appropriate technical terms, spelt correctly.

(a) (i) Name the type of nuclear division that occurs in plant growth.

(ii) Draw the chromosomes within the cell outline below as they would appear during metaphase of nuclear division. Assume the diploid number of chromosomes is four.
(iii) Cytokinesis follows nuclear division. After cytokinesis, the cells elongate due to water uptake by osmosis.

Fig. 3.1 shows three plant cells. The value shown in each cell refers to the water potential, $\Psi$, in kPa.

Draw arrows on Fig. 3.1 below to show the movement of water between cells R, S and T.

![Fig. 3.1](image)

(b) Fig. 3.2, on the insert, shows the stump of a tree with new branches growing from the stump. New growth in a stem or trunk comes from the cambium, which is situated between the xylem and phloem tissues. Explain why the new branches in Fig. 3.2 are seen growing from a position just under the bark of the cut surface.

(c) Name one other location where growth occurs in a plant.
(d) Look at the areas labelled L on Fig. 3.2. These are areas of loosely packed cells in the bark called lenticels. Lenticels allow gases to diffuse into the living tissues of the trunk.

Suggest why lenticels are essential to the survival of large multicellular plants and explain why similar structures are not found in large multicellular animals.

[2]
[Total: 10]
Fig. 4.1 shows the oxygen dissociation curves for fetal haemoglobin (A) and adult haemoglobin (B).

(a) (i) Curve A represents fetal haemoglobin.

Explain why the fetal haemoglobin curve is to the left of the adult haemoglobin curve.
(ii) Sickle cell anaemia is an inherited disorder in which haemoglobin crystallises when the partial pressure of oxygen \((pO_2)\) is low. The red blood cells change shape and oxygen transport is disrupted.

Treatment with drugs, such as hydroxyurea, can stimulate adults to produce fetal haemoglobin rather than adult haemoglobin.

Suggest why this treatment might be of benefit to adults with sickle cell anaemia.

[Total: 9]
(a) List three reasons why a large, multicellular animal, such as a mammal, needs a transport system.
Fig. 1.1 shows the nervous pathways that coordinate heart action.

Above the diagram is a trace showing the electrical activity associated with one heart beat.
(b) (i) State the full name given to a trace showing the electrical activity of the heart.

(ii) Identify the components of the heart labelled A and B on Fig. 1.1.

A ...................................................................................................................................................

B ...................................................................................................................................................

(c) (i) During the electrical stimulation of the heart, there is a short delay between the excitation of the atria and excitation of the ventricles.

Explain why this delay is essential.

(ii) The Purkyne tissue carries the excitation wave down the septum to the apex of the heart.

Explain why the excitation wave is carried to the apex.

[Total: 10]
(a) Fig. 2.1, shows a yeast cell with scars resulting from its reproductive process.

(i) Name the process of asexual reproduction in yeast.

(ii) Outline the process of asexual reproduction in yeast.
(b) (i) A yeast cell can continue producing new cells until its surface is covered by scars.

The surface area of a sphere is given by the formula \(4\pi r^2\), where \(\pi = 3.14\).

The area of a circle is given by the formula \(\pi r^2\).

Assuming that the cell in Fig. 2.1 contained no scars, calculate how many potential new cells could be produced by this cell.

Show your working.

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

Answer =

(ii) Even when the environmental conditions are perfect, one yeast cell rarely produces the calculated number of potential new cells.

Suggest why the reproductive potential of the yeast cell is not reached.

(a) The structure of cell membranes can be described as ‘proteins floating in a sea of lipids’. This membrane structure allows certain substances to pass through freely whereas other substances cannot.

State the term used to describe a membrane through which some substances can pass freely but others cannot.

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

[1]

(b) Complete the following paragraph about cell membranes, using the most appropriate terms.

The model of cell membrane structure is called the ________ model. Phospholipid bilayers with specific membrane proteins account for the ability of the membrane to allow both passive and ________ transport mechanisms. Ions and most polar molecules are insoluble in the phospholipid bilayer. However, the bilayer allows diffusion of most non-polar molecules such as ________ Protein channels, which may be gated, and ________ proteins enable the cell to control the movement of most polar substances.

[4]

(c) One function of membranes that is not mentioned in (b) is cell signalling.

(i) State what is meant by cell signalling.

_____________________________________________________________________________________________________
_____________________________________________________________________________________________________
_____________________________________________________________________________________________________

</tbody>
</table>

(i) The student calculated the surface area:volume ratio of sphere B as 2:1.
Calculate the surface area:volume ratio of sphere A. Show your working.

(ii) How does the surface area:volume ratio of sphere B differ from that of sphere A?

(iii) Single-celled organisms generally have a surface-area to volume ratio more like that of sphere A than sphere B.
Explain why.
(b) The lungs in the mammalian body are well developed to allow effective exchange of gases. Describe the features of the lungs that make them effective organs for the exchange of gases.

In your answer, you should use appropriate technical terms, spelled correctly.

(c) Fig. 3.1 shows the trace from a spirometer. A spirometer is a device designed to measure the volume of air entering and leaving the lungs. A chamber in the spirometer contains soda lime to absorb the carbon dioxide released by respiration. The measurements shown were recorded from a healthy 17-year-old student at rest.

(i) Explain why the volume of air in the spirometer drops slowly over the first minute.
(ii) After one minute, the student was asked to breathe in as deeply as possible and then breathe out as much as possible.

The resulting change in the trace is shown in Fig. 3.2 as $X$.

State the term given to measurement $X$.
(a) The transport system in mammals is a double circulatory system driven by a pump (the heart).

Explain what is meant by a *double circulatory system*.
(b) Fig. 4.1 gives information about the relative thickness of the walls of three chambers of the heart:

- left ventricle
- right ventricle
- right atrium

(i) State which of these chambers are identified by the letters D, E and F.

D ............

E ............

F ............

(ii) Explain, with reference to its function, why the wall of chamber F is much thicker than the walls of chambers D and E.
Haemoglobin, a pigment found in the blood of mammals, has an important role in the transport of respiratory gases. Each haemoglobin molecule contains haem groups. In the lungs, oxygen binds with the atom of ___________________________ in each haem group. The maximum number of molecules of oxygen that can be carried by one molecule of haemoglobin is ___________________________. In areas like muscle tissue where the partial pressure of oxygen is low, oxygen dissociates from the haem group. This dissociation is increased by the presence of carbon dioxide; this is called the ___________________________. Most of the carbon dioxide produced in respiring tissues diffuses into the red blood cells where the enzyme ___________________________ catalyses a reaction leading to the production of hydrogen ions and hydrogen carbonate ions. The hydrogen ions combine very readily with haemoglobin to form a compound known as ___________________________. The effect of this is to increase the release of oxygen from haemoglobin.
Transpiration is the loss of water from plants by evaporation. Fig. 5.1 shows a potometer, an apparatus used to estimate transpiration rates.

(a) Transpiration itself is not measured directly by a potometer. State what is measured by this apparatus.

(b) Describe how the apparatus should be set up to ensure that valid measurements can be made. 

In your answer, you should make clear how the steps in the process are sequenced.
A student investigated the transpiration rates of two different plants A and B.

The results of the investigation are shown in Table 5.1.

### Table 5.1

**Table 5.2**

(i) Identify the tube that contains the following organelles:

- nuclei
- ribosomes
- mitochondria
- lysosomes

(ii) Which of the organelles listed in (i) is the smallest in size?
(a) The lignin in the xylem vessel walls of plants and the C-rings of cartilage in the mammalian trachea perform an important role.

(i) Explain why lignin is essential in the wall of a xylem vessel.

(ii) Explain why cartilage is essential in the trachea.

(b) All living organisms exchange substances with their external environment.

The following data apply to an average person:

- the surface area of the body is approximately 1.8 m$^2$
- the volume of the body is approximately 0.07 m$^3$
- the surface area of the lungs is approximately 70 m$^2$.

Comment on the significance of this information for gas exchange.
Membranes are found both at the surface of cells and within cells.

(a) State two functions of membranes within cells.

(b) Describe the arrangement and functions of two named components of a cell surface membrane. 

In your answer you should use appropriate technical terms, spelled correctly.

(c) (i) Which component of a cell membrane becomes more fluid as temperature increases?

(ii) Which component of a cell membrane denatures as temperature increases?
Liver cells contain membrane-bound organelles called peroxisomes. These organelles contain catalase, an enzyme that breaks down hydrogen peroxide to release oxygen gas.

A student carried out an investigation on catalase using the following procedure:

- two identical sized cubes were cut from a piece of fresh liver
- one cube was frozen overnight and then defrosted
- the other cube was stored in the refrigerator
- both cubes were returned to room temperature and were placed in separate test tubes containing equal volumes of 2% hydrogen peroxide solution.

The student observed that the cube of liver that had been frozen and defrosted, bubbled significantly more than the cube that had been refrigerated.

Suggest an explanation for this result.
